# How many filters we should apply

**Hypothesis**
Natural images are stationary
Visual features are common for different parts of one or multiple image

**Conclusion**
It is not required to use different filters for different spatial locations in the image (in other words, **apply same filter for ALL positions in the image**)

*Apply Red filter to detect ears in the whole image (not necessarily in the middle of the image)*
*Apply filter to detect nose in the whole image*
*Apply Green filter to detect edges in the whole image*
